

# Cocktail sort

Class	Sorting algorithm
Data structure	Array
Worst case performance	$O(n^2)$

**Cocktail sort**, also known as **bidirectional bubble sort**, **cocktail shaker sort**, **shaker sort** (which can also refer to a variant of selection sort), **ripple sort**, **shuttle sort** or **happy hour sort**, is a variation of bubble sort that is both a stable sorting algorithm and a comparison sort. The algorithm differs from bubble sort in that it sorts in both directions on each pass through the list. This sorting algorithm is only marginally more difficult to implement than bubble sort, and solves the problem with so-called turtles in bubble sort.

## Pseudocode

The simplest form of cocktail sort goes through the whole list each time:

```
procedure cocktailSort( A : list of sortable items ) defined as:
do
  swapped := false
  for each i in 0 to length( A ) - 2 do:
    if A[ i ] > A[ i + 1 ] then // test whether the two elements are in the wrong order
      swap( A[ i ], A[ i + 1 ] ) // let the two elements change places
      swapped := true
    end if
  end for
  if swapped = false then
    // we can exit the outer loop here if no swaps occurred.
    break do-while loop
  end if
  swapped := false
  for each i in length( A ) - 2 to 0 do:
    if A[ i ] > A[ i + 1 ] then
      swap( A[ i ], A[ i + 1 ] )
      swapped := true
    end if
  end for
  while swapped // if no elements have been swapped, then the list is sorted
end procedure
```

The first rightward pass will shift the largest element to its correct place at the end, and the following leftward pass will shift the smallest element to its correct place at the beginning. The second complete pass will shift the second largest and second smallest elements to their correct places, and so on. After  $i$  passes, the first  $i$  and the last  $i$  elements in the list are in their correct positions, and do not need to be checked. By shortening the part of the list that is sorted each time, the number of operations can be halved (see bubble sort).

```
procedure cocktailSort( A : list of sortable items ) defined as:
  // `begin` and `end` marks the first and last index to check
  begin := -1
```

```
end := length( A ) - 2
do
  swapped := false
  // increases `begin` because the elements before `begin` are in correct order
  begin := begin + 1
  for each i in begin to end do:
    if A[ i ] > A[ i + 1 ] then
      swap( A[ i ], A[ i + 1 ] )
      swapped := true
    end if
  end for
  if swapped = false then
    break do-while loop
  end if
  swapped := false
  // decreases `end` because the elements after `end` are in correct order
  end := end - 1
  for each i in end to begin do:
    if A[ i ] > A[ i + 1 ] then
      swap( A[ i ], A[ i + 1 ] )
      swapped := true
    end if
  end for
while swapped
end procedure
```

## Differences from bubble sort

Cocktail sort is a slight variation of bubble sort. It differs in that instead of repeatedly passing through the list from bottom to top, it passes alternately from bottom to top and then from top to bottom. It can achieve slightly better performance than a standard bubble sort. The reason for this is that bubble sort only passes through the list in one direction and therefore can only move items backward one step each iteration.

An example of a list that proves this point is the list (2,3,4,5,1), which would only need to go through one pass of cocktail sort to become sorted, but if using an ascending bubble sort would take four passes. However one cocktail sort pass should be counted as two bubble sort passes. Typically cocktail sort is less than two times faster than bubble sort.

Another optimization can be that the algorithm remembers where the last actual swap has been done. In the next iteration, there will be no swaps beyond this limit and the algorithm has shorter passes. As the Cocktail sort goes bidirectionally, the range of possible swaps, which is the range to be tested, will reduce per pass, thus reducing the overall running time.

## Complexity

The complexity of cocktail sort in big O notation is  $O(n^2)$  for both the worst case and the average case, but it becomes closer to  $O(n)$  if the list is mostly ordered before applying the sorting algorithm, for example, if every element is at a position that differs at most  $k$  ( $k \geq 1$ ) from the position it is going to end up in, the complexity of cocktail sort becomes  $O(k * n)$ .

Cocktail sort is also briefly discussed in the book *The Art of Computer Programming*, along with similar refinements of bubble sort. In conclusion, Knuth states about bubble sort and its improvements (Knuth 1998, p. 110):

“ But none of these refinements leads to an algorithm better than straight insertion [that is, insertion sort]; and we already know that straight insertion isn't suitable for large  $N$ . [...] In short, the bubble sort seems to have nothing to recommend it, except a catchy name and the fact that it leads to some interesting theoretical problems. ”

—D. E. Knuth, *The Art of Computer Programming*, Vol. 3: Sorting and Searching, Second Edition, Addison-Wesley, 1998.
